# GREENFOND MPR

a mixture of stonecrops

---

GREENFOND MPR is a mixture of stonecrops adequately selected in the form of shoots for use on extensive green roofs

GREENFOND MPR is a mixture of sedum shoots supplied in at least 5 varieties in the form of freshly cut rhizomes from plantations and delivered directly to the investment area. A perfect alternative to greening an extensive roof where we do not care about a quick visual effect like in the case of a stonecrop mat. The economic aspect of such a solution compensates us with the time waiting for the final effect of the green roof. We achieve the initial greening effect after about 3 months after sowing.

**SOWING METHOD:**

Loosen and gently crush the substrate layer and evenly spread the rhizomes, and then thoroughly water the entire sown surface. Rhizome consumption in the case of dry sowing is 50-80 g / m<sup>2</sup>

**CARE:**

After sowing, the rhizomes must be kept at a constant humidity until the plants are rooted in the substrate. The length of the rooting process depends on weather conditions. After finishing sowing, thoroughly water at the end of each day. Ensure that the substrate layer is well hydrated to ensure proper conditions for rooting of plants. Every year in the spring, plants should be enriched with nitrogen fertilizer.

**STORAGE:**

The rhizomes should be sown on the day of delivery. Rhizomes to be sown at a later date should be unpacked, gently unfolded on a dry substrate and stored in a cool and shady room for no longer than 2-3 days.
